

give a very short overview how this repo works with the rest of the platform folders like grn-...data/ and the normal workspace/data same fo rartifacts, runs, notebooks,scripts, tests etc, whats the relationship with the folders created by prepare_runpod_workspace, also how would the platform actually use this folder? stay brief i want to move on to the second layer.

prepare_runpod_workspace creates the **platform-level storage layout**.
prepare_nca_art_workspace creates one **research code repository** inside that platform.

```
/workspace/  
  repos/  
    nca-art-grn/      # code repo created by prepare_nca_art_workspace  
  data/              # shared datasets, candidate libraries, imported inputs  
  runs/              # platform-level experiment run outputs  
  artifacts/         # reusable outputs, reports, figures, models  
  models/            # model weights / local model caches  
  checkpoints/       # training checkpoints
```

Inside nca-art-grn/ , folders are mostly **project-local views** of that work:

```
nca-art-grn/  
  src/               # actual Python package: simulator, DSL, ART, NCA, search  
  configs/           # experiment configs that point to /workspace/data and /workspace/runs  
  notebooks/         # exploration and paper figures  
  scripts/           # developer entrypoints for local runs  
  tests/             # repo validation  
  data/              # small examples, schemas, tiny fixtures, not big datasets  
  runs/              # local/dev smoke runs only  
  artifacts/         # repo-local generated examples only
```

So the rule should be:

```
small example data lives in repo/data  
real research data lives in /workspace/data  
  
local smoke outputs live in repo/runs  
real experiment outputs live in /workspace/runs  
  
example/demo artifacts live in repo/artifacts  
important reusable results live in /workspace/artifacts  
  
source code, configs, tests, notebooks, scripts live in repo
```

The platform uses the repo like this:

```
config prepares the repo, env, paths, and packages  
researchscientist runs code from nca-art-grn/  
Runpod jobs mount /workspace and execute repo scripts/configs  
Agentfield later submits experiments that call this repo's CLI/modules  
Paperclip later shows those Agentfield runs, status, artifacts, and results
```

In short:

```
/workspace = shared platform state  
/workspace/repos/nca-art-grn = research engine source code  
Agentfield = orchestrates this engine later  
Paperclip = makes those orchestrated runs visible and controllable
```
